During a disease outbreak, formal qualitative information is rarely collected in a systematic manner and thus tends to become anecdotal (and no longer relevant to the response). Nevertheless, it is key to better understand the views and perspectives of the people/groups living in the communities we work with. In DRC, Oxfam learned that during an outbreak, communities’ perceptions can rapidly change depending on the different stage of the outbreak, the context, and the direction in which the emergency response is heading. As this information can vary widely across different groups of people and different locations, Oxfam developed a mobile tool to enable staff to capture qualitative information, in real time, on perceptions and beliefs related to a disease outbreak.

Previous experience with mobile data collection tools had revealed that the use of ICTs to capture information can support faster, and more accurate, data collection in a way that avoids placing a significant burden on programme staff. By systematically capturing informal information through a mobile device, Oxfam was able to transform anecdotal information shared verbally into more purposeful evidence that was documented and used to inform response activities. The information was stored in a single database, enabling the categorisation of data into common themes—once cross-checked and analysed, the themes and recurrences identified allowed Oxfam to adapt its activities and tailor its interventions according to different groups and locations.

A first pilot project took place in Haiti, in the North Region/ Cap Haitian, during the Cholera outbreak from March to June 2018. An updated version of the CPT was then trialled in North Kivu (DRC), from the beginning of the Ebola outbreak in October 2018 for a period of twelve months. The CPT pilot projects were funded during the first phase by Seed Innovation Funds from Oxfam Intermón, and then by WASH Innovation Funds from the Global Humanitarian Team.

The 2018 North Kivu Ebola outbreak is a textbook example of the importance of tracking community perceptions.

In the early hours of the outbreak, activities followed a top-down approach, disregarding local habits and sensitivities, and aggravating resistance from the community – response efforts therefore took place in a high-tension context, rife with misinformation and general distrust from communities.

Data collection runs a risk of bias
As the CPT data is non-exhaustive and there are often language barriers in the field, biases inevitably appear during the collection process. Detecting trends can therefore be challenging. To mitigate this, managers have a key role to play, ensuring that sufficient data is collected, identifying gaps and encouraging collection teams to remain proactive and motivated – this requires regular meetings to maintain morale, particularly in the event of collection fatigue.

External communication and effective advocacy are key
At response coordination level, an absence of functional collaborative mechanisms means that information can easily be lost. As such, advocating for effective feedback mechanisms is complementary to the collection and processing of community perceptions.

Documenting the CPT is crucial
The DRC pilot project identified that the documentation of the CPT process should be done systematically and more effectively moving forwards. To continue building on the learnings from this project, monitoring and documentation are areas that CPT teams should pay close attention to.
On a daily basis, community perceptions were captured by approximately 30 Oxfam staff in Butembo, Beni, Mangina and Goma. With the tool downloaded on their mobile phones, staff could actively listen to perceptions in the field and complete the SurveyCTO form in real time.

On a weekly basis, the collected perceptions were extracted and compiled by the MEAL team and analysed and discussed by the technical teams. Thanks to the design of the tool, the data collected was made available to programme teams on a weekly basis, allowing upcoming activities to be planned around the CPT outcomes.

Every Saturday, the PHP team discussed the analytical report and decided on key actions for the following week. Whenever a perception appeared to grow in importance, the team could decide to address the topic during a community dialogue. For instance, in September 2019, as a fear of chlorinated water was identified as a growing trend amongst women, an awareness-raising session was organised to discuss the matter.

The CPT, combined with wider formative research by other actors, was used to influence the vaccination protocol in its inclusion of pregnant and lactating women.

When shared externally, all data collected through the CPT resulted in a stronger overall understanding of the context of the response. Supplemented by additional studies, such as UNICEF’s Cellule d’Analyse en Sciences Sociales (CASS), the different pillars and services of the Ebola response were better informed and therefore more effectively tailored to the context.

Regular analysis of the collected data made it possible to swiftly address obstacles. In the early hours of the response, the CPT data revealed that communities were concerned about the response team’s lack of knowledge of local dialects. Oxfam worked with communities to set up a “Comité Cellule”, a community structure composed of locally elected members who were responsible for implementing action plans in their community.

Concerns related to the response itself (including medical care and vaccinations) were shared with the advocacy team. For example, Oxfam identified that women were concerned about pregnant and lactating women being excluded from the vaccination protocol. Oxfam worked with communities to set up a “Comité Cellule”, a community structure composed of locally elected members who were responsible for implementing action plans in their community.

The CPT was active in DRC from October 2018 to March 2020.

**HOW did it work?**

**The presence of Comité Cellule in our health area reduced resistances. We recommend to set up similar systems in the entire city of Beni**

**Perception collected in Beni in June 2019**

**“Please be discreet when bringing us hygiene kits, we fear our neighbours might think we collaborate with response teams”**

**Perception collected in Katwa in April 2019**

**“We find the tool really easy to use: when returning from activities with the community, it just takes a minute to fill in the SurveyCTO form in the car. The second we reach the office and have a WIFI connection, the data is automatically sent to the server”**

**PHP officer, Beni**

**“Sick people get scared when response teams address them in French”**

**Perception collected in Beni in November 2018**

**“If a lactating woman becomes listed as a high-risk contact, how can she protect herself when she cannot even get the vaccine?”**

**Perception collected in Biakato in March 2019**

**“The community prefers washing their hands with soap rather than chlorine because the latter smells strange”**

**Perception collected in Mabalako in September 2019**

**“If a lactating woman becomes listed as a high-risk contact, how can she protect herself when she cannot even get the vaccine?”**

**Perception collected in Biakato in March 2019**

**“The presence of Comité Cellule in our health area reduced resistances. We recommend to set up similar systems in the entire city of Beni”**

**Perception collected in Beni in June 2019**

**“The community prefers washing their hands with soap rather than chlorine because the latter smells strange”**

**Perception collected in Mabalako in September 2019**
During the Ebola response, the use of the CPT brought additional value to all stages of the continuous community engagement process. There were four key objectives to the tool’s use, each interconnected to serve multiple purposes:

1. To better document ongoing context analysis: Data collected through the CPT can be multifunctional:
   - 1. It can be used to support risk analysis and make immediate programmatic adjustments. For instance, in April 2019 the PHP team in Katwa adjusted their visibility and presence in the field following sensible comments and perspectives expressed in the health areas of Wayene and Muchanga.
   - 2. It can help to design projects based on priority needs expressed by the community. In September 2019, Oxfam responded to a call for access to essential services required by communities affected by Ebola – the CPT captured the fact that poor access to water was a frequently expressed concern, so a WASH project was subsequently developed to meet this need.
   - 3. When shared externally, it can contribute to deeper analysis of the overall operating context. Oxfam’s findings supplemented studies from UNICEF’s Cellule d’Analyse en Sciences Sociales (CASS) and from the Social Science in Humanitarian Action Platform (SSHAP). These studies aimed at informing the pillars of the response that focused on community dynamics and perceptions, so that services provided could be better tailored to the context.

2. To swiftly adapt programmes based on communities’ perceptions: The immediate analysis of the collected data makes it possible to swiftly address obstacles. In the early hours of the Ebola response, the CPT data revealed that communities had concerns about response teams consisting mostly of outsiders who spoke neither Kiswahili nor Kinande. They raised the importance of receiving information through people they know and trust. Oxfam worked with communities to set up various “comités cellules”, community structures composed of locally elected members who could implement action plans within their community.

3. To effectively advocate on behalf of communities: Perhaps one of the most significant values of the CPT is the possibility it provides to document and quantify concerns and suggestions from the community, for a more impactful community-based advocacy. For example, during 2019, Oxfam identified that women were concerned that pregnant and lactating women were excluded from vaccination. The CPT, combined with wider formative research (conducted by UNICEF’s CASS), was used to influence the vaccination protocol. Consequently, pregnant and lactating women who had been in direct contact with an Ebola patient were now being vaccinated. The information collected was also used to advocate for changes in the burial protocol, leading to less women being involved in the carrying of coffins during safe and dignified burials, which respects local norms and traditions.

4. To successfully monitor changes in comprehension and behaviours: The CPT does not collect quantitative data and is therefore not considered to be scientifically robust. However, the regular reports it provides can help identify trends and assumptions, thereby informing teams of topics that remain relevant and important to the communities.

For example, throughout the early stages of the Ebola outbreak, signs and symptoms were of key concern to community members. In 2019, this tendency changed, and most concerns were thereafter linked with the coordination of the response.

CPT data can also reveal community satisfaction in relation to a concern that has been addressed or can demonstrate that a former concern has since metamorphosed into a new one.
